Abstract

This paper presents a rule-based fuzzy logic controller applied to a scalar closed loop Volts/Hz induction motor (IM) control with slip regulation and its simulation results. The IM is model in terms of d-q windings, with synchronous frame associated with the frequency $\omega_s$ of the stator excitation. The results obtained in the simulation are interesting, considering the presence of strong non-linearity in the IM model. A fuzzy logic control for a speed control of Induction motor the simulation developed by using Fuzzy MATLAB Toolbox and SIMULINK. The fuzzy logic controller is also introduced to the system for keeping the motor speed to be constant when the load varies. Because of the low maintenance and robustness induction motors have many applications in the industries.

1. Introduction

The Fuzzy Logic Toolbox draws upon these capabilities to provide a powerful tool for fuzzy system design, analysis, and simulation. This technical brief describes the use of the Fuzzy Logic Toolbox to solve a typical control design problem. Fuzzy logic can make control engineering easier for many types of tasks. It can also add control where it was previously impractical, as applications such as fuzzy-controlled washing machines have shown. However, fuzzy control need not be a dramatic departure from conventional control techniques such as proportional integral derivative (PID) feedback systems. As this technical brief demonstrates, fuzzy logic can be used to simplify the scheduling of two different controllers.

2. Fuzzy Logic Controller (FLC)

The simulation developed by using Fuzzy MATLAB Toolbox for SIMULINK and fuzzy logic. MATLAB Fuzzy logic Toolbox is use to design fuzzy logic controller. Basically, the Fuzzy Logic controller consists of four basic components: fuzzification, a knowledge base, inference engine, and a defuzzification interface. The addition of fuzziness to data in fuzzy logic is called the fuzzification.

2. V/F Control

A discussion of induction motor control theory is beyond the scope of this document. We will mention here only the salient points of VF control. The base speed of the induction motor is directly proportional to the supply frequency and the number of poles of the motor. Since the number of poles is fixed by design, the best way to vary the speed of the induction motor is by varying the supply frequency. The torque developed by the induction motor is directly proportional to the ratio of the applied voltage and the frequency of supply. By varying the voltage and the frequency, but keeping their ratio constant, the torque developed can be kept constant throughout the speed range [4]
Where: \( V \) = applied voltage, \( f \) = supply frequency, \( e_{emf} \) = counter e.m.f [5]

Figure 3 shows the typical torque-speed characteristics of the induction motor, supplied directly from the main supply. Figure 4 shows the torque-speed characteristics of the induction motor with V/F control. Other than the variation in speed, the torque-speed characteristics of the V/F control reveal the following:

- At base speed, the voltage and frequency reach the rated values. We can drive the motor beyond the base speed by increasing the frequency further. However, the applied voltage cannot be increased beyond the rated voltage. Therefore, only the frequency can be increased, which results in the reduction of torque. Above the base speed, the factors governing torque become complex. [4]

- The acceleration and deceleration of the motor can be controlled by controlling the change of the supply frequency to the motor with respect to time. [4]

4. Induction Motor

In the control of any power electronics drive system (say a motor), to start with a mathematical model of the plant is required. This mathematical model is required further to design any type of controller to control the process of the plant. The induction motor model is established using a rotating \((d, q)\) field reference (without saturation) concept [6].

The power circuit of the 3-φ induction motor is shown in the Fig. 5. The equivalent circuit used for obtaining the mathematical model of the induction motor is shown in the Fig. 6. An induction motor model is then used to predict the voltage required to drive the flux and torque to the demanded values within a fixed time period. This calculated voltage is then synthesized using the space vector modulation. [6]

7. Conclusion

An estimation of fuzzy logic techniques applied to the control of induction motor was presented. The fuzzy logic approach is feasible and can be an interesting alternative to conventional control, even when the system model is known.
